

Professor Notes About the “1-Sample Z-Test” Homework

- There must be a table of output from `z.test()` for the problems that require R. You must then label this table and refer to it directly for steps 6, 7, 8, and 11.
- In step 11, one must refer to the values of the confidence interval, lower bound, or upper bound. One does not refer to the specific value from the null hypothesis when interpreting the confidence region.
- Make sure to provide evidence for your statements. Don't just say “the sample is large”, rather say “the sample is large because $n=32 > 30$.” In addition, don't just say “... because a quantitative variable was measured on one population”, rather say “a quantitative variable (elk density) was measured on one population (‘plots in Banff National Park’).”
- It is not possible for the p-value to be zero. If the p-value is very small (i.e., less than a rounded 0.0001) then we generally write “ $p < 0.00005$.” It is, however, acceptable to show the p-value in scientific notation.
- Do not say “sample population” as there is no such thing. There is a “sample” (of the population) and there is a “population” but there is no “sample population.”
- Be specific about which distribution you are referring to ... it is the population distribution in a 1-sample Z-test.

Elk Density in Banff

1. $\alpha = 0.10$
2. $H_O : \mu = 8$, $H_A : \mu > 8$, where μ is the mean Elk density in Banff.
3. A 1-sample Z-test is required because a quantitative variable (Elk density) was measured on individuals from one population (plots in Banff National Park) and σ is known (given in background).
4. An observational sample that is not obviously random was selected.
5. The assumptions are met because $n = 15$ and population is approximately normal (given in background) and σ is known.
6. The statistic is $\bar{x} = 9.35$ Elk per km^2 (Table 1).

Table 1. Results from the one-sample z-test for testing that the mean density of elk in ALL plots in Banff is greater than 8 per km^2 .

```
z = 2.6194, n = 15.000, Std. Dev. = 2.000, Std. Dev. of the sample mean =  
0.516, p-value = 0.004404  
90 percent confidence interval:  
8.690876      Inf  
sample estimates:  
mean of elk  
9.352667
```

7. The test statistic is $z = 2.619$ (Table 1).
8. The p-value is $p = 0.0044$ (Table 1).
9. The H_O is rejected because the $p\text{-value} < \alpha$.
10. The annual density of elk appears to be greater than 8 per km^2 .
11. A 90% lower confidence bound is required. Thus, one is 90% confident that the mean annual density of elk is more than 8.69 per km^2 (Table 1).

Credit Card Limits

1. $\alpha = 0.10$.
2. $H_O : \mu = 630$, $H_A : \mu > 630$, where μ is the mean credit card limit for all companies.
3. A one-sample Z-test is required because a quantitative variable (credit score) was measured on individuals from one population (all credit card companies) and σ is known (given in background).
4. An observational sample, with no evidence of randomness, was selected.
5. The assumptions are met because $n \geq 30$ and σ is known.
6. The statistic is $\bar{x} = 636.86$.
7. The test statistic is $z = \frac{636.86 - 630}{\frac{5}{\sqrt{44}}} = 9.11$
8. The p-value is < 0.00005 .
9. The H_O is rejected because the p-value $< \alpha$.
10. It appears that the credit threshold is greater than 60. Thus, it appears that the credit card companies have increased the threshold for issuing a credit card.
11. A 90% lower confidence bound with $Z^* = -1.282$. Thus, $636.86 - 1.282 \frac{5}{\sqrt{44}}$ or $636.86 - 0.97 = 635.89$. Therefore, one is 90% confident that the mean cutoff score for ALL companies is greater than 635.89.

R Appendix

```
library(NCStats)
setwd('C:/aaaWork/Books/IntroStats/HW/')
elk <- read.csv("Elk.csv")
( elk.z <- z.test(elk,mu=8,sd=2,alt="greater",conf.level=0.90) )

( distrib(636.86,mean=630,sd=5/sqrt(44),lower.tail=FALSE) )
( distrib(0.90,type="q",lower.tail=FALSE,lower.tail=FALSE) )
```
